HEY Guidelines for the management of Toxicities associated with immune checkpoint inhibitors.

Ipilimumab (anti-CTLA4 Mab), nivolumab and pembrolizumab (anti-PD-1 Mab) are being introduced in the management of a variety of metastatic malignancies including malignant melanoma, renal cancer and lung cancer. The use of such medications are expected to become more prevalent as research identifies additional indications.

The immune checkpoint inhibitors (ICPIs) share a list of immune-mediated toxicities induced by the deregulation of the immune system which is the basis of the mode of action of these agents. Significant attention needs to be given for managing patients experiencing toxicity from ICPIs since they often resemble toxicity caused by cytotoxic chemotherapy but management needs to be very specific often quite diverse from algorithms developed for cytotoxics.

Awareness of the possible immune-mediated toxicities associated with these agents within the context of units managing patients with acute presentation of symptoms while being treated with ICPIs is crucial for their safe and appropriate management in order to avert unnecessary morbidity or even mortality.

In the following sections we describe the major categories of immune-mediated toxicities caused by these agents and the principles of their management.

Specialist advice will need to be sought early in the management of severe toxicity.

The CTCAE v4 criteria are used throughout the document to grade toxicity.

**Principles**

The following principles have been published by the manufacturer of nivolumab and ipilimumab as part of risk minimisation material produced as part of regulatory application reflecting the products’ SPC and may serve as basic guidelines for the management of toxicity of this class of agents.

“Early identification of adverse reactions and timely intervention are an important part of the appropriate use of nivolumab or nivolumab in combination with ipilimumab

Patients should be monitored continuously (including at least up to 5 months after the last dose) as an adverse reaction with nivolumab or nivolumab in combination with ipilimumab may occur at any time during or after discontinuation of therapy.

If immunosuppression with corticosteroids is used to treat an adverse reaction, a taper of at least 1 month duration should be initiated upon improvement.

Rapid tapering may lead to worsening or recurrence of the adverse reaction.

Non-corticosteroid immunosuppressive therapy should be added if there is worsening or no improvement despite corticosteroid use.

Prophylactic antibiotics should be used to prevent opportunistic infections in patients receiving immunosuppressive therapy.

Nivolumab or nivolumab in combination with ipilimumab should not be resumed while the patient is receiving immunosuppressive doses of corticosteroids or other immunosuppressive therapy.
When nivolumab is administered in combination with ipilimumab, if either agent is withheld, the other agent should also be withheld. If dosing is resumed after a delay, either the combination treatment or nivolumab monotherapy could be resumed based on the evaluation of the individual patient.

Nivolumab or nivolumab in combination with ipilimumab must be permanently discontinued for any severe immune-related adverse reaction that recurs and for any life threatening immune-related adverse reaction. Nivolumab or nivolumab in combination with ipilimumab should also be permanently discontinued for Grade 4 or recurrent Grade 3 immune-related adverse reactions, and for Grade 2 or 3 immune-related adverse reactions that persist despite treatment modifications or if a reduction of corticosteroid dose to 10 mg prednisone or equivalent per day cannot be achieved.”

Diarrhea / Colitis

**Signs and symptoms**
- Watery, loose or soft stools
- Abdominal pain
- Mucus or blood in stool

Rule out infectious and disease-related aetiologies (stool cultures).

Inform Treating Oncologist

grade 4
If symptoms resolve or improve to grade, taper steroids over 4 weeks and continue immunotherapy after that
If symptoms resolve monotherapy could be resumed for grade 3 diarrhoea after corticosteroid tapering, combination CTLA4 and PD-1 treatment should be discontinued for both grade 3 and 4 diarrhea
Taper steroids over >2 months

**Immunotherapy modification**

OMIT/DEFER ICPI treatment
Discontinue immunotherapy (permanently for relapse or grade 4 or for combination CTLA4/PD1 and grade 3 diarrhea)

---

**Endocrinopathies**

Severe endocrinopathies, including hypothyroidism, hyperthyroidism, adrenal insufficiency, hypophysitis, diabetes mellitus, and diabetic ketoacidosis have been observed.

Monitor patients for clinical signs and symptoms of endocrinopathies (see box below) and for hyperglycaemia and for changes in thyroid function (at the start of treatment, periodically during treatment, and as indicated based on clinical evaluation)

**Signs and Symptoms**

- Fatigue
- Headache
- Mental status change
- Abdominal pain
- Unusual bowel habits
- Hypotension
- Visual disturbances
- Weight change
- Excessive thirst
- Passing a greatly increased amount of urine
- Increased appetite with a loss of weight
- Feeling tired, drowsy, weak, depressed, irritable and generally unwell

Other non-specific symptoms which may resemble other causes such as brain metastasis or underlying disease.

Unless an alternate aetiology has been identified, signs or symptoms of endocrinopathies should be considered immune-related

• Assess: TSH, T4, T3, ACTH, LH, FSH & cortisol, prolactin, and testosterone. MRI of the pituitary when hypophysitis is suspected.
• Inform treating Oncologist.
• For asymptomatic grade 1, endocrinopathies early specialist endocrinology advice is recommended but immunotherapy can continue
• For symptomatic endocrinopathies: immunotherapy is withheld.
• For isolated symptomatic hyperthyreoidism propranolol and prednisolone 0.5-1mg.kg/day are indicated. Before initiating thyroxine replacement adrenal insufficiency must be ruled out with short synacten test if any features of hypoadrenalism are present.
• For symptomatic hyperthyroidism and hypophysitis corticosteroids are initiated such as methylprednisolone IV at 1-2mg/kg/day or IV/oral equivalents if acute gland inflammation is suspected.
• Hormone replacement therapy must me initiated as needed for hypothyreoidism, hypophysitis, hypoadrenalism, diabetes.
• Early referral to endocrinology is recommended in all cases.
• The Nivolumab and SPC recommends permanent discontinuation of the drug, for all grade 4 endocrinological events as well as for grade 3 adrenal insufficiency.
• The Pembralizumab SPC recommends withholding or discontinuing pembrolizumab for grade 3 and 4 hypophysitis and hyperthyroidism.
• In general, for grade2-3 endocrinopathies that are under control with hormone replacement and if symptoms are resolved, treatment can continue with close monitoring of endocrine function.
• When steroids are used for physiological replacement immunotherapy can resume, but high dose steroids need to have been slowly tapered before resumption in other cases.
• Gonadotrophin and TSH can recover but ACTH insufficiency rarely does.

For severe endocrinopathy: Grade 3,4, severely unwell patient, dehydration, hypotension or shock
• Admit patient- URGENT endocrinology advice
• Immediate hydrocortisone 100 mg intravenously (IV) every 6 hours
• Commence IV hydration if indicated
• Exclude infection/sepsis
• Assess: TSH, T4, T3, ACTH, LH, FSH & cortisol, prolactin, testosterone prior to IV steroids
• ECG
• Withhold next cycle of immunotherapy
• MR imaging brain with pituitary cuts

• SUSPECT ADRENAL CRISIS

Defined by severe dehydration, hypotension or shock
Pneumonitis

Signs and symptoms
- Breathing difficulties or cough
- Radiographic changes (e.g. focal ground glass opacities, patchy filtrates)
- Dyspnoea
- Hypoxia

Rule out infectious and disease-related aetiologies

</table>
Grade 1 rash
- Regular monitoring
- Consider anti-histamines
- Consider topical steroids
- Continue immunotherapy

Grade 2 rash
- Increase monitoring
- Anti-histamines
- Localised rash:
  Topical steroidal based cream
  1% Hydrocortisone (acetate) cream bd for face
  Betamethasone valerate (Betnovate) 0.1% cream to other sites

- Extensive rash: prednisolone 0.5-1mg/kg od x 3-7 days-max. 60mg/day
- Withhold treatment until ≤ Grade 1

Grade 3 rash
Withhold immunotherapy until symptoms resolve and management with steroids is complete
Sever rash should be treated with high-dose corticosteroids i.e 1-2mg.kg/day or BD of IV methylprednisolone or equivalents.
Specialist dermatology advice

**Steroids need to be tapered over >4 weeks**

Grade 4 rash, >50% skin surface, generalised, exfoliative, ulcerative, bullous dermatitis
Permanently discontinue immunotherapy
Admit patient
Urgent specialist Dermatology advice

- High-dose IV corticosteroid therapy (eg, methylprednisolone 2 mg/kg once/twice or equivalent eg hydrocortisone)
- Regular ob’s and fluid balance
- Anti-histamines-hydroxyzine 25mg qds max. 100mg daily
Topical emollient cream - cetraben

**Steroid tapper over >2 months**

**Stevens-Johnson Syndrome**

Urgent admission and early specialist referral, will require referral to specialist centre

**Renal toxicity / Nephritis**

**Signs and symptoms**

- Asymptomatic increase in serum creatinine
- Other abnormal kidney function tests
- Decreased volume of urine

Rule out disease–related aetiologies

Inform treating oncologist

**Myasthenic syndrome**

- For suspected immune-related adverse reactions, adequate evaluation should be performed to confirm aetiology or exclude other causes.
- Based on the severity of the adverse reaction, immunotherapy should be withheld and corticosteroids administered.
- Early specialist advice should be sought.
- Upon improvement, immunotherapy may be resumed after corticosteroid taper (taper > 4 weeks).
- Immunotherapy should be permanently discontinued for any severe immune-related adverse reaction that recurs and for any life-threatening immune-related adverse reaction.

**From Pembrolizumab SPC**

**Withhold KEYTRUDA for any of the following:**

- Grade 2 pneumonitis.
- Grade 2 or 3 colitis.
- Grade 3 or 4 endocrinopathies.
- Grade 2 nephritis.
- Aspartate aminotransferase (AST) or alanine aminotransferase (ALT) greater than 3 and up to 5 times upper limit of normal (ULN) or total bilirubin greater than 1.5 and up to 3 times ULN.
- Any other severe or Grade 3 treatment-related adverse reaction.
- Resume KEYTRUDA in patients whose adverse reactions recover to Grade 0-1.
- Permanently discontinue KEYTRUDA for any of the following:
  - Any life-threatening adverse reaction (excluding endocrinopathies controlled with hormone replacement therapy).
  - Grade 3 or 4 pneumonitis or recurrent pneumonitis of Grade 2 severity [see Warnings and Precautions].
  - Grade 3 or 4 nephritis [see Warnings and Precautions].
  - AST or ALT greater than 5 times ULN or total bilirubin greater than 3 times ULN. For patients with liver metastasis who begin treatment with Grade 2 AST or ALT, if AST or ALT increases by greater than or equal to 50% relative to baseline and lasts for at least 1 week Grade 3 or 4 infusion-related reactions [see Warnings and Precautions].
  - Inability to reduce corticosteroid dose to 10 mg or less of prednisone or equivalent per day within 12 weeks.
  - Persistent Grade 2 or 3 adverse reactions (excluding endocrinopathies controlled with hormone replacement therapy) that do not recover to Grade 0-1 within 12 weeks after last dose of KEYTRUDA.
  - Any severe or Grade 3 treatment-related adverse reaction that recurs [see Warnings and Precautions].

From Nivolumab SPC

- When nivolumab is administered in combination with ipilimumab, refer to the Summary of Product Characteristics for ipilimumab prior to initiation of treatment. Immune-related adverse reactions have occurred at higher frequencies when nivolumab was administered in combination with ipilimumab compared with nivolumab as monotherapy. Most immune-related adverse reactions improved or resolved with appropriate management, including initiation of corticosteroids and treatment modifications (see section 4.2).
- Cardiac adverse events and pulmonary embolism have also been reported with combination therapy. Patients should be monitored for cardiac and pulmonary adverse reactions continuously, as well as for clinical signs, symptoms, and laboratory abnormalities indicative of electrolyte disturbances and dehydration prior to and periodically during treatment. Nivolumab in combination with ipilimumab should be discontinued for life-threatening or recurrent severe cardiac and pulmonary adverse reactions.

- Patients should be monitored continuously (at least up to 5 months after the last dose) as an adverse reaction with nivolumab or nivolumab in combination with ipilimumab may occur at any time during or after discontinuation of therapy.

- For suspected immune-related adverse reactions, adequate evaluation should be performed to confirm aetiology or exclude other causes. Based on the severity of the adverse reaction,
nivolumab or nivolumab in combination with ipilimumab should be withheld and corticosteroids administered. If immunosuppression with corticosteroids is used to treat an adverse reaction, a taper of at least 1 month duration should be initiated upon improvement. Rapid tapering may lead to worsening or recurrence of the adverse reaction. Non-corticosteroid immunosuppressive therapy should be added if there is worsening or no improvement despite corticosteroid use.

- Nivolumab or nivolumab in combination with ipilimumab should not be resumed while the patient is receiving immunosuppressive doses of corticosteroids or other immunosuppressive therapy. Prophylactic antibiotics should be used to prevent opportunistic infections in patients receiving immunosuppressive therapy.
- Nivolumab or nivolumab in combination with ipilimumab must be permanently discontinued for any severe immune-related adverse reaction that recurs and for any life-threatening immune-related adverse reaction

References
